The underlying assumption of studies of

brain and behavioral plasticity is that if behavior changes, there must be some change in organization or properties of the neural circuitry that produces the behavior.

Conversely, if neural networks are changed by experience, there must be some corresponding change in the functions mediated

Experience is a major stimulant of brain plasticity in animal species as diverse as insects and humans. It is now clear that experience produces multiple, dissociable changes in the brain including increases in dendritic length, increases (or decreases) in spine density, synapse

formation, increased glial activity, and altered metabolic activity.

These anatomical changes are correlated with behavioral differences between subjects with and without the changes.

What Is Neuroplasticity.

Just in case you 've managed to miss all the hype, neuroplasticity is an umbrella term referring to the ability of your brain to reorganize itself, both physically and functionally, throughout your life due to your environment, behavior, thinking, and emotions. types of studies look at brain plasticity and behavior in birds. These include studies of bird song, imprinting, and one-trial learning.

Studies of bird song have been reviewed extensively elsewhere (e.g. Bottjer & Arnold 1997) and largely have focused on the development of neurons and their connectivity.

In response to sensory inputs, environmental challenges, and even injury, the brain remodels itself and we 're able to learn and change our behavior. Plasticity peaks in childhood, a time when our brains are primed to change in response to experiences.

Depression is associated with several changes in brain plasticity.

Converging lines of evidence point to a critical role of brain derived neurotrophic factor (BDNF) in depression. Animal and human studies have shown that BDNF levels are reduced during depression yet increased
